

## ■ **\*\*Regression Results — ELI5 Interpretation\*\***

Intercept = 0.722

bill\_total\_usd = 0.094

party\_size = 0.180

gender\_Male = -0.027

is\_smoker\_Yes = -0.084

$R^2 = 0.469$

### ■ **\*Plain-English summary:\***

For every \$1 higher bill, the tip goes up by about \$0.09.

Larger parties tip more, while smoking tables and male servers tip slightly less.

The model explains about 47% of tip variation — decent, not perfect.

### ■ **\*\*ELI5 Summary:\*\***

Imagine you're guessing someone's tip using clues: bill size, group size, smoking, and server gender.

Each clue nudges your guess a little up or down. Bigger bills and groups mean higher tips.

Smokers and male servers slightly lower. Your guessing game is right about half the time.
